Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

This invention relates to a head mountable display according to the preamble of claim 1.

A very advantageous head mounted display system is disclosed in US-A-4,859,030. This system utilizes a rather complex optical arrangement, usable in a rather restricted space, for directing light from a source, such as a cathode ray tube, to a spherical reflector from which the light is then reflected through a tuned optical filter and, as collimated rays, is directed to the eye of the pilot so that he sees the image at infinity combined with his normal field of view through the optical filter and spherical combiner. In order to make a compact display system with high efficiency, it is necessary to tilt it so that the center of curvature is not at the pilot's eye since if it were, the light from the CRT would have to strike the combiner perpendicular so as to be reflected to the eye along the same path. This then would result in a reduction of light from the CRT to one quarter of its intensity and would also reduce the light from the surrounding scene by fifty percent. This was solved in the above mentioned patent by tilting the combiner so that the rays from the filter to the combiner were not reflected back to the filter along the same path and by utilizing special coatings on the filter so that the amount of light lost on reflection at predetermined angles (those from the CRT) was very small but the amount of light transmitted by the filter at certain angles (those from the combiner) was very large. Tilting of the spherical combiner did, however, introduce additional aberrations, a tilt distortion, and a mapping distortion such as the "Keystone" effect which had to be corrected in the known apparatus with additional optical elements and off-center components to provide a distortion free view for the pilot.

While the known system is quite satisfactory for performing all of the desired functions, the number of components and their off-center arrangement has made the system difficult to assemble and align and it is heavier and more costly to produce than desirable.

Further head mountable displays where holograms are used as diffractive elements are known from EP-A-0 288 365 and GB-A-2 006 463. Furthermore, EP-A-0 305 096 discloses a head-up display where diffractive elements are used to reduce the physical size of a relay unit.

Finally, EP-A-0 526 067 which is published prior to the international filing date of the present application but later than the priority date claimed, discloses an optical display system which uses at least one diffractive element to counter at least partially chromatic dispersion of the system.

The present invention overcomes the problems with the prior art head mounted display by utilizing one or more diffractive surfaces in the optical system. These diffractive surfaces are shaped by known techniques to correct not only for chromatic and aspheric aberration, but also to produce the necessary tilt and decenter func-

tions for aberration correction and distortion mapping correction; and thus may be substituted for several optical elements of the prior art apparatus and thus reduce the number of optical elements and eliminate off-center lenses therein. The diffractive surfaces are formed on existing surfaces of the system so as to further prevent an increase the number of components.

The hybrid system of the present invention contains only simple spherical lenses that are fewer in number and with a spherical combiner, involve no off-axis components and yet which provides all the same corrections as in the prior art. When used with a spherical combiner, and with two diffractive surfaces, the number of lenses can be reduced from eight, some of which are non-spherical and/or non-centered, as seen in the above mentioned patent, to seven centered spherical lenses, thus making alignment and assembly of the system much easier. Further reductions in number of components is obtainable by using a non-spherical (e.g. elliptical) combiner which suffers no astigmatism from the combiner and only four lenses are then needed but, although none of the lenses are aspheric, two of the lenses are now decentered.

Use of diffractive surfaces in optical systems is known in the prior art. For example, "Head Up Displays" have employed diffractive elements, usually in combination with the combiner therein so as to act as an optical filter and/or focusing and collimating means. Diffractive surfaces have also been used in telescopes to correct for chromatic and spherical aberrations but neither head up displays nor telescope systems require the very close tolerances and small available space encountered in head mounted systems and the design concepts cannot normally be interchanged. Furthermore, there has heretofore been no optical systems which have employed diffractive surfaces to remove tilted and decentered optical elements or to correct for distortion mapping such as the Keystone effect.

A more complete understanding of the invention will be obtained upon an examination of the following specification and claims read in connection with the attached drawings, where

Fig. 1 shows a system utilized in the prior art;

Fig. 2 shows the present invention utilizing a spherical combiner; and

Fig. 3 shows the apparatus of the present invention utilizing an elliptical combiner.

The helmet mounted display of Fig. 1 is like that shown in the above-referred to US-A-4,859,030. In this system, an image from a cathode ray tube surface 12 passes through an optical relay system 14 to a spherical combiner surface 16. More particularly, light rays from the optical relay system 14 is reflected from a tuned filter 18, which may be like that of the US patent, and then to the combiner 16 for reflection back through the filter 18 and are focused on the eye of a pilot 20. For simplicity,

the light rays are shown as three principal rays 21, 22 and 23 passing through the system. The rays 21, 22 and 23 emerge from the filter 18 as collimated wavefronts to produce an image of the CRT surface 12 at infinity so as to superimpose this image with the image of the surrounding scene being viewed by the pilot 20 through the combiner 16 and the filter 18.

It is seen in Figure 1 that the combiner 16 is tilted so that the optical axis of the eye and combiner are not collinear which allows the rays 21, 22 and 23 coming from the relay optics 14 to reflect off of filter 18 at different angles of incidence than the rays from combiner 16 and allow greater amounts of light for both the CRT image and the scene image by tuning the filter 18 as described in the US patent. As explained, however, this produces tilt errors, decentering and distortion mapping which must be corrected. Accordingly, the optical relay system 14 consists often optical elements, eight of which are lenses and that several of these lenses are non-spherical and/or off-centered. Each of the lenses and combinations of lenses performs a function such as correcting for chromatic aberration, correcting for aspheric aberration, producing the required tilt and decentering corrections, and for correcting distortion mapping. It is also seen that the number of elements produces a rather complex system which, it has been found, is difficult to assemble and align, and adds greatly to the weight and cost of the helmet mounted display.

Fig. 2 shows the present invention utilizing a simplified optical relay system 24 in combination with the spherical combiner 16 and the filter 18 to focus an image from the surface 12 of the CRT on the eye of the pilot 20 as was the case in Fig. 1. Again in Fig. 2, only three principal light rays 26, 28, and 30 are shown. Since the combiner 16 is spherical, it must be tilted and the rays 26, 28 and 30 passing from the cathode ray tube 12 to the eye of pilot 20 must be corrected for chromatic aberrations, spherical aberration, decentering, distortion mapping and tilt correction. Accordingly, in the present invention, diffraction surfaces shown as dashed lines 40 and 42 are introduced on two surfaces which for example may be the planar surfaces of two of the presently existing lenses. Diffraction surfaces 40 and 42 may be made by Binary Optic Microlithography, by diamond turning or any other suitable method and are shaped to counter balance the effects of the aberrations and errors. The image formed is, like that of Figure 1, at infinity so that the pilot observes the image along with the image of the scene he sees through the filter 18 and spherical combiner 16. It is seen that the optical system of Fig. 2 has reduced the number of optical elements involved to nine, only seven of which are lenses and all of which are spherical and coaxial. This has been made possible by utilizing the two diffractive surfaces 40 and 42 which perform the same function and replace several of the lenses of Figure 1.

Fig. 3 shows a yet simpler system utilizing an elliptical combiner 46, which is somewhat more difficult to

fabricate than a spherical combiner. In Fig. 3, the optical system 54 transmits an image from the surface of cathode ray tube 12 along paths such as shown by reference numerals 55, 56 and 57 through three spherical lenses, one prism and one reflecting surface to the filter 18 and then to the elliptical combiner 46 for reflection back through the filter 18 to the eye of pilot 20. In Fig. 3, two diffractive surfaces shown as dashed lines 58 and 59 are again used with each being formed on one surface of already existing lens within optical system 54. The diffractive surfaces 58 and 59 are again formed to correct for the aberrations and for the tilt, decentering and mapping distortions as was the case in Figure 2.

As before, three principle light rays 55, 56 and 57 are shown passing from the cathode ray tube surface 12 through the optical system 54 to be reflected from the filter 18 to the elliptical combiner 46 and then back through the filter 18 to be focused on the eye of the pilot 20 as an image at infinity so as to be combined with the view seen by the pilot through the filter 18 and combiner 46.

With an elliptical combiner the on-axis field point suffers no astigmatism from the combiner. Because the elliptical combiner can have the eye of the pilot 20 at one of the ellipse's foci, the astigmatism caused by tilting the combiner is substantially eliminated thus reducing the number of optical components even without the diffraction surfaces. With the diffraction surfaces 58 and 59, the system is simplified further to one having only three lenses all of which are spherical and centered. Thus the system of Figure 3 although involving a more difficult combiner to fabricate, yields a great weight reduction and, in addition, provides a better performance, a larger exit pupil, and is a very simple centered optical train compared to the conventional design of the prior art.

It is thus seen that we have provided an improved helmet mounted display which is at least as satisfactory as the prior art in performance and yet provides the performance with reduced number of optical elements to save on weight, alignment and cost.

Many changes and alterations will occur to those skilled in the art. For example, while two diffractive surfaces have been shown in connection with the preferred embodiments, one such surface may be satisfactory in some cases and three or more surfaces may be used to further refine the optics. Also, although shown in connection with the helmet mounted display of the Rotier patent, it may also find utility in other head mounted displays such as goggles. Accordingly, I do not wish to be limited to the disclosures used in connection with the preferred embodiments but intend only to be limited by the following claims.

Claims

1. A head mountable display which is corrected for ab-

errations and distortions in the image viewed by an observer (20), comprising:

- an image source (12);
 - a reflective image combiner (16,46);
 - a relay optical system (24,54) for transmitting the image from the source (12) to the combiner (16,46); and
 - means for mounting said image source (12), said image combiner (16,46) and said relay optical system (24) to the head of the observer (20), characterized in that said relay optical system (24,54) includes at least one diffractive surface (40,42,58,59) for correction of aberrations and distortions, and in that said at least one diffractive surface (40,42,58,59) is formed on a lens of said relay optical system (24).
2. Display according to claim 1 wherein the image combiner (16) is spherical and tilted so that the center of curvature is not at the observer's eye.
 3. Display according to claim 1 wherein the combiner (16) is elliptical.
 4. Display according to claim 2 or 3 wherein the image combiner (16) is partly transparent so that the observer (20) can see the surrounding scene therethrough combined with an image from said image source (12).
 5. Display according to claim 1 having a second diffractive surface (40,42,58,59) being formed on a lens.
 6. A method of correcting aberrations and distortions in the image viewed by an observer (20) in a head mountable display containing an image source (12), a reflective image combiner (16,46) which is partly transparent so that the observer (20) can see the surrounding scene therethrough combined with an image from said image source (12); and a relay optical system (24,54) comprising a plurality of lens elements, characterized by the step of:
 - diffracting light on a diffraction grating (40,42,58,59) formed on the surface of at least one lens element of said relay optical system (24,54).

Patentansprüche

1. Am Kopf montierbares Display, welches für Aberrationen und Verzeichnungen in dem durch einen Beobachter (20) betrachteten Bild korrigiert ist, aufweisend:

eine Bildquelle (12);
einen reflektierenden Bildkombinierer (16,46);
ein optisches Relaysystem (24,54) zur Übertragung des Bildes von der Quelle (12) zu dem Kombinierer (16,46); und
Mittel zur Anordnung der Bildquelle (12), des Bildkombinierers (16,46) und des optischen Relaysystems (24) an dem Kopf des Beobachters (20), dadurch gekennzeichnet, daß das optische Relaysystem (24,54) wenigstens eine beugende Oberfläche (40,42,58,59) für die Korrektur der Aberrationen und Verzeichnungen aufweist und daß die wenigstens eine beugende Oberfläche (40,42,58,59) auf einer Linse des optischen Relaysystems (24) gebildet ist.

2. Display nach Anspruch 1, wobei der Bildkombinierer (16) sphärisch ist und geschwenkt ist, so daß sich das Zentrum der Biegung nicht im Auge des Beobachters befindet.
3. Display nach Anspruch 1, wobei der Kombinierer (16) elliptisch ist.
4. Display nach Anspruch 2 oder 3, wobei der Bildkombinierer (16) teilweise transparent ist, so daß der Beobachter (20) die umgebende Szene durch ihn kombiniert mit einem Bild von der Bildquelle (12) sehen kann.
5. Display nach Anspruch 1, mit einer zweiten beugenden Oberfläche (40,42,58,59), die auf einer Linse gebildet ist.
6. Verfahren zur Korrektur von Aberrationen und Verzeichnungen in dem durch einen Beobachter (20) in einem am Kopf montierten Display betrachteten Bild mit einer Bildquelle (12), einem reflektierenden Bildkombinierer (16,46), welcher teilweise transparent ist, so daß der Beobachter (20) die umgebende Szene kombiniert mit einem Bild von der Bildquelle (12) sehen kann und mit einem optischen Relaysystem (24,54), das mehrere Linsenelemente umfaßt, gekennzeichnet durch den Schritt:
 - Beugung des Lichtes auf einem Beugungsgitter (40,42,58,59), das auf der Oberfläche wenigstens eines Linsenelementes des optischen Relaysystems (24,54) gebildet ist.

Revendications

1. Système d'affichage pouvant être monté sur la tête qui est corrigé sur le plan des aberrations et des déformations dans l'image observée par un observateur (20), comportant :

une source d'image (12) ;
un dispositif de combinaison d'image réfléchis-
sant (16, 46) ;

un système de relais optique (24, 54) destiné à
transmettre les images provenant de la source
(12) au dispositif de combinaison d'image (16,
46) ; et

des moyens destinés à monter ladite source
d'image (12), ledit dispositif de combinaison
d'image (16, 46) et ledit système de relais op-
tique (24) sur la tête de l'observateur (20), ca-
ractérisé en ce que ledit système de relais op-
tique (24, 54) comprend au moins une surface
de diffraction (40, 42, 58, 59) destinée à la cor-
rection des aberrations et des déformations, et
en ce que au moins ladite surface de diffraction
(40, 42, 58, 59) est formée sur une lentille dudit
système de relais optique (24).

2. Système d'affichage selon la revendication 1, dans
lequel le dispositif de combinaison d'image (16) est
sphérique et incliné de telle sorte que le centre de
courbure n'est pas au niveau de l'oeil de l'observa-
teur.

3. Système d'affichage selon la revendication 1, dans
lequel le dispositif de combinaison (16) est ellipti-
que.

4. Système d'affichage selon la revendication 2 ou 3,
dans lequel le dispositif de combinaison d'image
(16) est partiellement transparent de sorte que l'ob-
servateur (20) peut voir la scène environnante com-
binée avec une image provenant de ladite source
d'image (12).

5. Système d'affichage selon la revendication 1, ayant
une deuxième surface de diffraction (40, 42, 58, 59)
qui est formée sur une lentille.

6. Procédé de correction des aberrations et des défor-
mations dans l'image observée par un observateur
(20) dans un système d'affichage pouvant être
monté sur la tête contenant une source d'image
(12), un dispositif de combinaison d'image réfléchis-
sant (16, 46) qui est partiellement transparent
de sorte que l'observateur (20) peut voir la scène
environnante combinée avec une image provenant
de ladite source d'image (12), et un système de re-
lais optique (24, 54) comportant plusieurs éléments
de lentille, caractérisé par l'étape de diffraction de
la lumière sur un réseau de diffraction (40, 42, 58,
59) formé sur la surface d'au moins un élément de
lentille dudit système de relais optique (24, 54).
